VEDA TECHNOLOGY | DESCRIPTIVE STATISTICS PRIMER

Purpose	Calculate and interpret mean, median, mode, standard deviation, and percentiles for key numeric columns.
Objective	Build intuition for when to use each descriptive statistic and what it reveals about a distribution.
Tools covered	Excel / spreadsheet analysis; Python; Pandas (workflow notes included in the Method & Python sheet).
Dataset	Iris dataset: 150 observations, four numeric measurements in centimetres, and a species label. This is a commonly used public teaching dataset.
Deliverable 1	Summary statistics table for 4 numeric columns (within the requested 3–5 columns).
Deliverable 2	Short written interpretation of centre, skew clues, spread, and the middle 50% of values.
How to use	Start with Summary Statistics, then read Interpretation, then inspect Raw Iris Data. The workbook includes definitions, method notes, Python code, and interview answers.
Important note	Mean-vs-median comparison is a quick clue, not a formal skewness test. Standard deviation is most useful alongside the mean and in context.
